Dual operational transconductance amplifier

NE5517/5517A

DESCRIPTION

The NE5517 contains two current-controlled transconductance amplifiers, each with a differential input and push-pull output. The NE5517 offers significant design and performance advantages over similar devices for all types of programmable gain applications. Circuit performance is enhanced through the use of linearizing diodes at the inputs which enable a 10dB signal-to-noise improvement referenced to 0.5% THD. The NE5517 is suited for a wide variety of industrial and consumer applications and is recommended as the preferred circuit in the Dolby* HX (Headroom Extension) system.

Constant impedance buffers on the chip allow general use of the NE5517. These buffers are made of Darlington transistor and a biasing network which changes bias current in dependence of I_{ABC}.
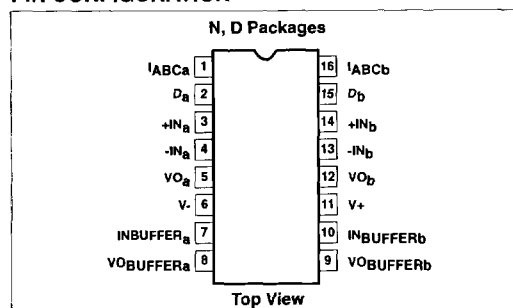

Therefore, changes of output offset voltages are almost eliminated. This is an advantage of the NE5517 compared to LM13600. With the LM13600, a burst in the bias current I_{ABC} guides to an audible offset voltage change at the output. With the constant impedance buffers of the NE5517 this effect can be avoided and makes this circuit preferable for high quality audio applications.

FEATURES

- Constant impedance buffers
- ΔVBE of buffer is constant with amplifier IBIAS change
- Pin compatible with LM13600
- Excellent matching between amplifiers
- Linearizing diodes
- High output signal-to-noise ratio

PIN CONFIGURATION

N, D Packages

I_{ABCa}	1	16	I_{ABCb}
D_a	2	15	D_b
$+IN_a$	3	14	$+IN_b$
$-IN_a$	4	13	$-IN_b$
VO_a	5	12	VO_b
$V-$	6	11	$V+$
$IN_{BUFFERa}$	7	10	$IN_{BUFFERb}$
$VO_{BUFFERa}$	8	9	$VO_{BUFFERb}$

ORDERING INFORMATION

DESCRIPTION	TEMPERATURE RANGE	ORDER CODE	DWG #
16-Pin Plastic Dual In-Line Package (DIP)	0 to +70°C	NE5517N	0406C
16-Pin Plastic Dual In-Line Package (DIP)	0 to +70°C	NE5517AN	0406C
16-Pin Small Outline (SO) Package	0 to +70°C	NE5517D	0005D

ABSOLUTE MAXIMUM RATINGS

SYMBOL	PARAMETER	RATING	UNIT
V_S	Supply voltage[1]		
	NE5517	36 V_{DC} or ±18	V
	NE5517A	44 V_{DC} or ±22	V
P_D	Power dissipation, T_A=25°C (still air)[2]		
	NE5517N, NE5517AN	1500	mW
	NE5517D	1125	mW
V_{IN}	Differential input voltage	±5	V
I_D	Diode bias current	2	mA
I_{ABC}	Amplifier bias current	2	mA
I_{SC}	Output short-circuit duration	Indefinite	
I_{OUT}	Buffer output current[3]	20	mA
T_A	Operating temperature range		
	NE5517N, NE5517AN	0°C to +70	°C
V_{DC}	DC input voltage	$+V_S$ to $-V_S$	
T_{STG}	Storage temperature range	-65°C to +150°C	°C
T_{SOLD}	Lead soldering temperature (10sec max)	300	°C

NOTES:
1. For selections to a supply voltage above ±22V, contact factory
2. The following derating factors should be applied above 25°C
   N package at 12.0mW/°C
   D package at 9.0mW/°C
3. Buffer output current should be limited so as to not exceed package dissipation.

DC ELECTRICAL CHARACTERISTICS[1]

CIRCUIT DESCRIPTION

The circuit schematic diagram of one-half of the NE5517, a dual operational transconductance amplifier with linearizing diodes and impedance buffers, is shown in Figure 1.

1. Transconductance Amplifier

The transistor pair, Q_4 and Q_5, forms a transconductance stage. The ratio of their collector currents (I_4 and I_5, respectively) is defined by the differential input voltage, V_{IN}, which is shown in equation 1.

$$V_{IN} = \frac{KT}{q} \ln \frac{I_5}{I_4} \qquad (1)$$

Where V_{IN} is the difference of the two input voltages

$KT \cong 26mV$ at room temperature (300°k).

Transistors Q_1, Q_2 and diode D_1 form a current mirror which focuses the sum of current I_4 and I_5 to be equal to amplifier bias current I_B:

$$I_4 + I_5 = I_B \qquad (2)$$

If V_{IN} is small, the ratio of I_5 and I_4 will approach unity and the Taylor series of In function can be approximated as

$$\frac{KT}{q} \ln \frac{I_5}{I_4} \approx \frac{KT}{q} \frac{I_5 - I_4}{I_4} \qquad (3)$$

Dual operational transconductance amplifier

NE5517/5517A

and $I_4 \cong I_5 \cong I_B$

$$\frac{KT}{q} \ln \frac{I_5}{I_4} \approx \frac{KT}{q} \frac{I_5 - I_4}{1/2 I_B} = \frac{2KT}{q} \frac{I_5 - I_4}{I_B} = V_{IN} \quad (4)$$

$$I_5 - I_4 = V_{IN} \frac{\left(I_B q\right)}{2KT}$$

The remaining transistors (Q_6 to Q_{11}) and diodes (D_4 to D_6) form three current mirrors that produce an output current equal to I_5 minus I_4. Thus:

$$V_{IN}\left(I_B \frac{q}{2KT}\right) = I_O \quad (5)$$

The term $\dfrac{\left(I_B q\right)}{2KT}$ is then the transconductance

of the amplifier and is proportional to I_B.

2. Linearizing Diodes

For V_{IN} greater than a few millivolts, equation 3 becomes invalid and the transconductance increases non-linearly. Figure 2 shows how the internal diodes can linearize the transfer function of the operational amplifier. Assume D_2 and D_3 are biased with current sources and the input signal current is I_S. Since

$I_4 + I_5 = I_B$ and $I_5 - I_4 = I_0$, that is:

$I_4 = (I_B - I_0)$, $I_5 = (I_B + I_0)$

For the diodes and the input transistors that have identical geometries and are subject to similar voltages and temperatures, the following equation is true:

$$\frac{T}{q} \ln \frac{\dfrac{i_D}{2} + I_S}{\dfrac{i_D}{2} - I_S} = \frac{KT}{q} \ln \frac{1/2(I_B + I_0)}{1/2(I_B - I_0)} \quad (6)$$

$$I_0 = I_S \frac{2 I_B}{I_D} \quad \text{for } |I_S| < \frac{I_D}{2}$$

The only limitation is that the signal current should not exceed I_D.

3. Impedance Buffer

The upper limit of transconductance is defined by the maximum value of I_B (2mA). The lowest value of I_B for which the amplifier will function therefore determines the overall dynamic range. At low values of I_B, a buffer with very low input bias current is desired. A Darlington amplifier with constant-current source (Q_{14}, Q_{15}, Q_{16}, D_7, D_8, and R_1) suits the need.

APPLICATIONS

Voltage-Controlled Amplifier

In Figure 3, the voltage divider R_2, R_3 divides the input-voltage into small values (mV range) so the amplifier operates in a linear manner.

It is:

$$I_{OUT} = -V_{IN} \cdot \frac{R_3}{R_2 + R_3} \cdot gM;$$

$$V_{OUT} = I_{OUT} \cdot R_L;$$

$$\boxed{A = \frac{V_{OUT}}{V_{IN}} = \frac{R_3}{R_2 + R_3} \cdot gM \cdot R_L}$$

(3) $g_M = 19.2\, I_{ABC}$

(g_M in μmhos for I_{ABC} in mA)

Since g_M is directly proportional to I_{ABC}, the amplification is controlled by the voltage V_C in a simple way.

When V_C is taken relative to $-V_{CC}$ the following formula is valid:

$$I_{ABC} = \frac{(V_C - 1.2V)}{R_1}$$

The 1.2V is the voltage across two base-emitter baths in the current mirrors. This circuit is the base for many applications of the NE5517.

NE5517/5517A

Figure 2. Linearizing Diode

Stereo Amplifier With Gain Control
Figure 4 shows a stereo amplifier with variable gain via a control input. Excellent tracking of typical 0.3dB is easy to achieve. With the potentiometer, R_P, the offset can be adjusted. For AC-coupled amplifiers, the potentiometer may be replaced with two 510Ω resistors.

Modulators
Because the transconductance of an OTA (Operational Transconductance Amplifier) is directly proportional to I_{ABC}, the amplification of a signal can be controlled easily. The output current is the product from transconductance×input voltage. The circuit is effective up to approximately 200kHz. Modulation of 99% is easy to achieve.

Voltage-Controlled Resistor (VCR)
Because an OTA is capable of producing an output current proportional to the input voltage, a voltage variable resistor can be made. Figure 6 shows how this is done. A voltage presented at the R_X terminals forces a voltage at the input. This voltage is multiplied by g_M and thereby forces a current through the R_X terminals:

$$R_X = \frac{R + R_A}{gM + R_A}$$

where g_M is approximately 19.21 µMHOs at room temperature. Figure 7 shows a Voltage Controlled Resistor using linearizing diodes. This improves the noise performance of the resistor.

Voltage-Controlled Filters
Figure 8 shows a Voltage Controlled Low-Pass Filter. The circuit is a unity gain buffer until X_C/g_M is equal to R/R_A. Then, the frequency response rolls off at a 6dB per octave with the -3dB point being defined by the given equations. Operating in the same manner, a Voltage Controlled High-Pass Filter is shown in Figure 9. Higher order filters can be made using additional amplifiers as shown in Figures 10 and 11.

Voltage-Controlled Oscillators
Figure 12 shows a voltage-controlled triangle-square wave generator. With the indicated values a range from 2Hz to 200kHz is possible by varying I_{ABC} from 1mA to 10µA.

The output amplitude is determined by
$I_{OUT} \times R_{OUT}$.

Please notice the differential input voltage is not allowed to be above 5V.

With a slight modification of this circuit you can get the sawtooth pulse generator, as shown in Figure 13.

APPLICATION HINTS
To hold the transconductance g_M within the linear range, I_{ABC} should be chosen not greater than 1mA. The current mirror ratio should be as accurate as possible over the entire current range. A current mirror with only two transistors is not recommended. A suitable current mirror can be built with a PNP transistor array which causes excellent matching and thermal coupling among the transistors. The output current range of the DAC normally reaches from 0 to -2mA. In this application, however, the current range is set through R_{REF} (10kΩ) to 0 to -1mA.

$$I_{DACMAX} = 2 \cdot \frac{V_{REF}}{R_{REF}} = 2 \cdot \frac{5V}{10k} = 1mA$$

TYPICAL VALUES: R_1 = 47k
R_2 = 10k
R_3 = 200Ω
R_4 = 200Ω
R_L = 100k
R_S = 47k
